Preconditioned Iterative Methods for Weighted Toeplitz Least Squares Problems

Saturday, 11 June 2022 12:15 (30 minutes)

In this talk we consider the problem of finding effective preconditioners for linear systems of the form Hx = y where

 $H = A^T DA + \lambda^2 L^T L where A and Larest ructured matrices (e.g., Toeplitz), Disadiagonal matrix, and \lambda \\ is a scalar. These linear systems can arise when iteratively computing approximations to nonlinear inverse problems. Typically in these applications the matrix <math>D$ changes at each nonlinear iteration, but A and L remain constant. Benzi and Ng [1] considered linear systems of this form, and proposed an effective variant of constraint preconditioning and a Hermitian/skew-Hermitian splitting (HSS) preconditioner. In this talk we consider an alternative approach based on low-rank matrix approximations.
